# 2007 New Mexico High School Youth Risk and Resiliency Survey (YRRS) Catron County

## Introduction

This report contains school district level results from the 2007 New Mexico High School Youth Risk and Resiliency Survey (YRRS), a statewide survey of public school students, grades 9-12. Statewide results are available in a series of modular reports entitled *Healthy Choices, Healthy Students: 2007 New Mexico High School Results*. County level reports are available on the NMDOH web site (<http://www.health.state.nm.us/epi/yrrs.html>). Together, these documents comprise a useful tool for those working on youth-related issues at the state and local level.

The YRRS is organized into two major content areas: risk behaviors and protective (resiliency) factors. Risk behaviors include behaviors associated with unintentional injury, violence, sadness and suicidal ideation, tobacco use, alcohol use, drug use, sexual activity, physical activity, and nutrition (Appendix B). Protective factors are measures of the positive and supportive relationships, experiences, activities, resources and values that encourage healthy youth development. Resiliency factors and related traits include caring and supportive relationships in the family, school, community and with peers; boundaries set by the family and school; positive peer support; meaningful participation and constructive use of time in school and outside of school; and impulsive and sensation seeking behavior (Appendix C).

Additionally, this report includes a section on academic measures and traits. These academic measures include getting good grades (mostly A's and B's), trying hard to do good work in school, planning to go to college, skipping or ditching school, coming to class with paper and something to write with, and completing homework.

## How to Read this Report

This report has three main sections, each of which consists of a set of bar charts. The first section presents the results of the major risk behaviors examined in the survey. Each category of risk behavior is presented with two or three kinds of bar charts. The first chart gives results for each year the YRRS had been administered (2001, 2003, 2005, and 2007). Another chart compares results for the school district to results for the entire state, and another compares the risk behaviors of boys to those of girls within the school district. Risk behaviors are defined in Appendix B.

The second section presents results for the academic measures and behaviors. As with the risk behaviors, there are three types of charts presenting results: one presenting trends, one presenting a comparison of the school district to the state, and another comparing boys to girls within the school district. Using the same three chart types, the third section of the report presents results for the resiliency/protective factors.

NOTE: County level YRRS reports are freely available. School district reports have been distributed to school district offices. School districts are encouraged to reproduce and share these reports with community groups concerned with prevention and health promotion. However, school district level results will not be released without express permission of the school district superintendent.

## Understanding the Charts - and A Word about Error Bars

The bar charts in this report present the percentage of students who reported engaging in any given risk behavior or who reported having any given protective factor. The height of the bars conveys the percentage of students reporting each trait, and provides a quick visual comparison between different groups of students reporting that trait. Underneath each set of bars is a table that presents the percentage of students who reported each trait. For instance, the chart on page 14, Behaviors Causing Unintentional Injury, shows that 8.9% of students in New Mexico rarely or never wore seatbelts, while 6.2% of students in Catron rarely or never wore seatbelts.

Because of the high cost and logistical complications involved in conducting a statewide survey, the YRRS was administered to a sample of students, rather than to every single student in each school district. Because YRRS data are about a *sample* of students, and not the entire student body, the results in this report are *estimates*. As with all estimates, there is some uncertainty associated with each of these estimates. On the charts in this report, this degree of uncertainty is represented by an error bar (or confidence interval). The error bar is the thin 'I' shaped line that extends above and below the end of each bar in a chart. One of the major influences on the size of the confidence interval or error bar is the number of participants in the survey. In general, this means that with more students participating in the survey, there will be a higher degree of confidence in the results (i.e., error bars will be smaller).

The proper interpretation of an error bar can be illustrated by looking at the chart below. This chart compares the New Mexico prevalence of smoking and of cocaine use to the United States prevalence for 2005, a previous survey year. The chart shows that the prevalence of current smoking was 25.7% in New Mexico and 23.0% in the United States. The error bar for the estimate of current smoking among New Mexico students extends approximately 4 percentage points in either direction, from 22.0% to 29.8%. This means that we are confident that the actual percentage of smokers in this group of students was between 22.0% and 29.8%. The error bar for the estimate current smoking in the US extends approximately 2.5 percentage points in either direction, from 20.7 to 25.3%. We are confident that the actual percentage of smokers among this group was between 20.7% and 25.3%.

Current Smoking and Current Cocaine Use  
Grades 9 - 12, 2005

How does knowing the upper and lower limits of our error bars help us? While it appears at first glance that New Mexico has a higher prevalence of smoking than the United States (25.7% vs. 23.0%), a closer look at the error bars shows a more complicated picture. The error bars for the New Mexico estimate (22.0% - 29.8%) and the US estimate (20.7% - 25.3%) overlap. Because of this overlap, we do not have a high degree of confidence that the prevalence of smoking in New Mexico is actually different from the prevalence in the United States. In other words, the difference between the prevalence of smoking in New Mexico and the United States is not statistically significant.

For cocaine use it also appears that in 2005, New Mexico had a higher prevalence than the United States (7.9% vs. 3.4%). The error bar for New Mexico extends from 6.6% to 9.5%, and the error bar for the United States extends from 2.8% to 4.4%. Because the higher extent of the US error bar (4.4%) is lower than the lower extent of the NM error bar (6.6%), these error bars do not overlap. For cocaine use, we are confident in saying that the New Mexico prevalence was higher than the US prevalence. In other words, the difference between the 2005 prevalence of smoking in New Mexico and the United States was a statistically significant difference.

For some small school districts, error bars have been removed from this report. With small populations, the number of students sampled can approach the total student population. In these cases, error bars would have limited meaning because with a high percentage of students surveyed, there is less uncertainty around the estimates than error bars suggest.

## **Methodology**

The YRRS was implemented in the fall semester of the 2007-08 school year. All public school districts in New Mexico were invited to participate in the 2007 YRRS. Of 89 districts statewide, 76 districts participated. From each participating school district, schools with students from 9th to 12th grades were selected to participate. The probability of selection of each school was proportional to the size of its 9th-12th grade population. In large school districts only some of the schools were selected to participate, while in small districts, all schools were selected. Classrooms were systematically selected from each school, and all students in each selected classroom were asked to participate.

In each participating school, a single day was arranged on which to administer the survey. Questionnaire forms and pencils were distributed to each student in participating classes, and students were asked to fill out the questionnaires independently of other students and without teacher assistance.

Questionnaires were electronically scanned, and data were analyzed using STATA 9.2, a statistical software program.

## **Limitations of the YRRS**

All information from the YRRS was self-reported by the participating students. While most questions on the YRRS come from nationally validated surveys, and data quality has been demonstrated to be very high in national surveys, there is no way to guarantee the truthfulness of the participants in any survey that relies on self-reporting.

A good response rate is one of the most important goals in conducting a survey. At the school district level, a response rate is the percentage of all students selected for the survey who complete and return a useable questionnaire form. At the state level, the response rate incorporates the participation of school districts and schools as well as the participation of students. An adequate response rate means that survey results are more likely to represent the actual student population. The statewide response rate for the 2007 YRRS was 60%, an adequate response rate to represent the population.

In order to achieve a 60% statewide response rate, we aimed for a 75% response rate from each participating school district. Most participating school districts met this target or were close to it. While the response rate was generally very good in participating schools, the overall response rate was driven down by the school districts that declined to participate.

## Participation in Catron County

The response rate for Catron County was 45%.

A high response rate produces survey results that are more representative of the student population. A response rate of at least 60% allows generalization of results to the entire student body. A response rate of 75% is excellent and allows a high degree of confidence in results. Because a high response rate means that more students have been surveyed, a high response rate will also be reflected in the error bars (i.e., with a higher response rate and more students included in the survey, error bars will be smaller and confidence intervals will be narrower). Response rates below 60% are considered low, and caution should be exercised in interpreting results. Low response rates indicate that the data may represent only students who participated in the survey and not necessarily the entire student body.
